AUTHOR: Ivenskiy, Yu.N.
TITLE: The design of control circuits with contactless elements
PERIODICAL: Referativnyy zhurnal, Elektrotehnika i energetika, no.3, 1962, 1, abstract 3 K3. (Vestn. elektroprom-sti, no.8, 1961, 41-44).
TEXT: Relay-contact control circuits are reduced to a certain combination of nodes that fulfil the logical operations 'And', 'Or', 'Not', 'Prohibited', 'Memory' and 'Time delay'. Reliable contactless control systems of long life may be constructed on the basis of contactless stepwise switching elements having the above-mentioned logical relationships between the input and output signals. The special features of these control systems must be allowed for in designing them; switching is not ideal, i.e. there is interference; the elements have many inputs and one output; and it is necessary to amplify the output signal to work the operating devices. The construction of

optimum contactless control systems is facilitated by using the laws of mathematical logic. Examples are given of desirable conversion in the typical relay-contact nodes and in nodes of contactless control systems. Two examples are given of construction of contactless control systems for machine tool drive.

TITLE: Problems in the design of control circuits and components for automated machining production lines (Experience of SKB-8)

SOURCE: Proyektirovaniye i ekspluatatsiya avtomaticheskikh liniy mekhanicheskoy obrabotki. Mosk. dom nauchno-tekhn. prop. Ed. by A.P. Vladziyevskiy. Moscow, Mashgiz, 1962. 68-87

TEXT: Designs adopted as a result of experience with electrical control systems for automatic production lines are described and their reasons discussed. The primary criteria are the reliability and endurance of the system. Communication engineering components in low voltage systems are preferred to medium voltage contactor systems. The advantages of low voltage systems can only be retained by paying full attention to their special requirements. The power supply unit is a three-phase transformer with rectifiers in a bridge arrangement having a low ripple factor and ensuring that the effect of filtering and spark suppression circuits on the supply voltage fluctuations is small.

Problems in the design ...

Protective devices based on maximum current and thermal protection are discussed. Detailed examples are given of control circuits based on time delay elements embodying RC circuits. One example is the control of a turntable used in standard unit type and specialized machine tools. Another example is an automatic production line wherein the machine tools consist of several detachable units. In this control scheme, relays signalling the initial position are used. The coil circuit of such relays contains the series contacts of limit switches which detect the initial position of the elements. The central control panel of such a production line is illustrated. The presence or absence of a hole sometimes forms a necessary element of detection in the control system. In the case of small holes, such inspection is accomplished by establishing that the drill is unbroken after drilling. The inspection is performed by a special feeler. The use of semiconductor amplifiers is described. The control of time delays is performed by means of a transistorized time relay operated by contactless logical elements. Voltage and temperature fluctuations have only a small effect. Details of installation design are discussed. There are 12 figures.

TITLE: At the XIth General Assembly in Toronto of the International Union of Geodesy and Geophysics (IUGG) (Na XI general'noy assambleye mezhdunarodnogo soyusa geodezii i geofiziki (IUGG) v Toronto)

PERIODICAL: Izvestiya Akademii nauk SSSR - Seriya geograficheskaya, 1958, Nr 2, pp 3-8 (USSR)

ABSTRACT: The XIth General Assembly of the International Union of Geodesy and Geophysics convened in Toronto from 3 to 14 September 1957. The USSR was represented by a delegation consisting of 54 scientists headed by Academician I.P. Bardin. The Soviet geographers G.A. Avsyuk, A.P. Gal'tsov, M.I. Iveronova and Yu.A. Meshcheryakov participated for the first time in a meeting of the Union. The conference was divided into various sections dealing with special fields. The conference heard the following Soviet reports: The Geodesists M.S. Molodenskiy, A.A. Izotov, Yu.D. Bulanzhe and M.I. Sinyagina on the achievements of Soviet science in the geodesy; V.V. Belousov, V.A. Magnitskiy, Ye.A. Lyubimova, V.I. Keylis-Borok and Yu.V. Reznichenko on seismological problems and questions concerning the physical structure of the Earth's deposits; G.A. Avsyuk on glacial research work

carried out in the USSR; A.M. Obukhov and A.S. Monin on meteorological questions, especially diffusion and convection. Special attention was paid to the reports of the Soviet scientists M.I. Sinyaginaya and Yu.A. Meshcheryakov on the study of present movements of the Earth crust in the European part of the USSR. M.I. Budyko dealt with the distribution of the components of the thermal balance of the Earth's surface. This report met with especially great interest since only the USSR has succeeded in preparing monthly charts on the components of the thermal balance all over the world, and what is even more important, in solving the problem of determining the evaporation taking place on the surface of dry land. Ye.P. Tolstik explorer of polar regions reported on Soviet research in the Arctic and Antarctic Zones within the International Geophysical Year. Due to the Soviet achievements in all these fields of science V.V. Belousov, Corresponding Member of the AS, USSR was elected Vice-President of the

TITLE: The Dependence of the Characteristic Temperature Determined by X-Ray Analysis on the Tin Concentration in Solid Cu-Sn Solutions

PERIODICAL: Vestnik Moskovskogo universiteta. Seriya 3, fizika, astronomiya, 1960, No. 4, pp. 52 - 58

TEXT: The authors report on measurements of the characteristic temperature θ_p in Cu-Sn alloys within a wide concentration range. These alloys were chosen because their modulus of elasticity ΔE varies considerably with concentration ($\Delta E/\Delta C = 500 \text{ kg/mm}^2$ per at% Sn). The characteristic temperatures were determined by X-ray analysis from the intensity ratios of the CuK(133) line at room temperature and at -196°C . For these measurements the authors chose copper-tin alloys in the α -phase with 2.35 at% tin (2 samples), 4.73 at% (2 samples), and 7.1 at% Sn (3 samples). The samples were produced from electrolytic copper and high-

the Tin Concentration in Solid Cu-Sn Solutions

purity tin, and were annealed for 24 - 48 hours at about 50°C. The degree of homogeneity was determined from the distinctness of the (133-024) doublet of X-ray powder patterns. A Geiger counter was used for the measurements. A curved quartz crystal served as a monochromator. The intensity of the monochromatic beam was checked by a monitor counter. Fig. 1 illustrates the concentration dependence of θ_p . With increasing tin concentration, θ_p rapidly decreases. The same holds for the quantity $m\theta_p^2$ which is proportional to the modulus of elasticity of the binding forces of the atoms (Fig. 2). θ_p and E are connected by the relation

$$\theta = \frac{h^{1/2}}{k} \left(\frac{3N}{4\pi} \right)^{1/3} \frac{E^{1/2}}{M^{1/3} q^{1/6} f^{1/2}(\sigma)}$$

(h - Planck's constant, k - Boltzmann constant, N - Avogadro constant, M - atomic weight, q - density, f(σ) - function of the Poisson ratio). At low tin concentrations, also the relation $\theta = K/E$ may be used, which leads to $\frac{\Delta\theta_p}{\Delta C\theta_p} = \frac{1}{2} \frac{\Delta E}{\Delta CE} = 2.0 \cdot 10^{-2}$ or

TITLE: Question of evaporation from the snow cover on the
USSR's territory

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 7, 1962, 63, ab-
stract 7V370 (Rol' snezhn. pokrova v prirodn. prot-
sessakh, M., AN SSSR, 1961, 36-53)

TEXT: It is shown that the empirical formula $E = (0.0075 + 0.0041 U_{1000}) (l_n - l_{200})$ allows the values of winter evaporation from
snow to be calculated from the data of meteorologic network obser-
vations with a precision sufficient for determining its role in the
water balance of a given territory. In this formula E is the mag-
nitude of evaporation from snow in mm/hr; l_n is the maximum water-
vapor tension in mb, determined from the snow surface's tempera-
ture; l_{200} is the air's absolute humidity in mb at a level 2 m from ✓

Card 1/5

Question of evaporation ...

S/169/62/000/007/122/149
D228/D307

the ground surface; and U_{1000} is the wind velocity in m/sec at a level of 10 m (at the wind vane height). These calculations, however, have yet to be done; they are laborious and require much time. The author recommends that the question of zoning a territory according to the value of evaporation from the snow cover should be approached as follows. Areas should be distinguished where the total magnitude of evaporation in the winter season comprises a value that is in the range of the accuracy of accounting for the maximum water reserves, which have accumulated in the snow cover, and hence merits no special attention. Then areas should be distinguished in which all components of the water balance and the winter evaporation in particular have to be strictly taken into account. Having assumed that the possible average for winter evaporation is 25 mm, the author demonstrates that its role in the water balance will have the least significance for those of the Soviet Union's territories, which are characterized by maximum water reserves of about 150 mm and more in the snow cover or by winters with much snow, having a maximum mean 10-day snow-cover depth

Card 2/5

Question of evaporation ...

S/169/62/000/007/122/149
D228/D307

of more than 50 cm. In this case the overall magnitude of evaporation from the snow surface will lie in a range in which the snow cover's water reserve can be accurately calculated from snow surveys. The climatic zoning of the USSR carried out by A. A. Grigor'yev and M. I. Budyko was used to zone the USSR according to the specific value of evaporation in the water balance of its separate territories. The author also enlisted G. D. Rikhter's data on the zoning and the characteristic of the snow cover regime on the USSR's territory. 6 areas were distinguished on the accompanying scheme. Area I includes territory with an unstable snow cover; in the water balance the role of evaporation from the snow cover's surface is small. Territories where the winter has much snow belong to Area II. Here the role of evaporation is slight, too, since its overall winter value amounts to less than 20% of the snow cover's water reserves and thus lies in the range in which these can be accurately calculated. Territories having winters with much snow and excessively wet climates, belong to Area III. Here the strict calculation of relatively small expenditures of the water balance's items can be of no great significance. Area IV includes ✓

Card 3/5

Question of evaporation ...

S/169/62/000/007/122/149
D228/D307

territories with little snow, though they are located in the zone of sufficiently wet climate. Territories situated in the dry climatic zone, belong to Area V; in them the role of winter evaporation is small. The author reckons that evaporation from the snow cover is highly significant in Area IV and V, and that it has to be considered in each kind of calculation for the water economy and the hydrology. Mountain regions belong to Area VI. Here the loss of snow in evaporation is significant only for mountain regions with little snow (Armyanskoye Highlands, the east part of the Glavnny Kavkazskiy Range, E. Tyan'-Shan', E. Pamirs). The estimation of the magnitude of evaporation from the snow cover acquires special interest in the period of thaw, since this quantity is usually not taken into account from the moment of determining the maximum water reserves up to the snow cover's disappearance. It is supposed that the type of spring above all determines whether the process of evaporation from snow, or the process of condensation on the surface, predominates in the period of thaw. Evaporation should prevail throughout springs of the radiation type. Conditions for the development of this process are unfavorable when there are

Card 4/5

Question of evaporation ...

S/169/62/000/007/122/149
D228/D307

springs of the advective type. In most cases the maximum magnitude of evaporation during the thaw varies from 0.4 to 1.0 mm/day on the USSR's territory. The average magnitude of evaporation in the period of thaw varies from 0.10 to 1.08 mm/day, comprising on an average 0.4 mm/day. If the duration of the snow cover's period of thaw is taken as 20 - 25 days, the magnitude of evaporation for this period will comprise 8 - 10 mm. 38 references. The Texture of Rolled α -Brass. G. S. Zhdanov and V. I. Tsvetkov [Zurnal Tekhnicheskoy Fiziki (J. Tech. Physics), 1934, 4, 911-914]. [In Russian.] The textures of copper and α -brass with different zinc contents and the pole figures (111), (200), and (220) for the three degrees of intensity, indicate that the texture of the metal depends on the zinc content up to 10% when the brass texture is established, and this changes only slightly with increase of zinc. Zinc produces a merging of the (111) and (100) textures of copper, but has no effect on the (112) texture as shown by the pole figures and by photographs taken with a special texture camera. The latter also indicates that the number of unoriented crystals increases with increase in the zinc content. The texture of α -brasses with a low zinc content is analogous to that of gold and silver.—N. A.

Effect of aluminum and vanadium on the recrystallization of iron and steel. V. I. Iversonova. *Zarudnye Lab.* 8, 187-193 (1939).—Iron and steel contg. addns. of Al and V were subjected to an x-ray examn. by the Debye method to det. the temp. of recrystnl. in relation to the compn. and to the no. of recrystl. grains in a unit vol. as a function of the temp. Al which enters the solid soln. in the lattice of α Fe raises strongly the starting temp. of recrystnl. while leaving unchanged the end temp. of recrystnl. V_2O_5 sharply raises the temp. of recrystnl. of the same steel. Presence of 6% Al raises recrystnl. temp. by 100° while as little as 0.1% V raises the starting temp. by 100° and the end temp. by 75°. Addns. of oxides of Al and V increased the no. of recrystl. centers considerably while changing the rate of growth very little.

*Atomic Diffraction of X-Rays in Copper-Zinc Alloys
A. V. Bemotkova and V. I. Livanova (Zhur. Tekhn. Fiziki,
1960, 22, (6), 606-609; Physics ab., 1961, 64, 371).--[In
Russian]. When a solid soln. is formed, the atoms of the
various kinds are in statistical disorder in the lattice. Taking
an atomic factor f_A , the mean value of the factors of the
interchangeable elements, if $C\%$ of the atoms A are replaced
by B atoms, the atomic factor is calculated thus: $100f_A =$
 $f_{A1}(100 - C) + f_{B1}C$, where f_{A1} and f_{B1} are the individual
atomic factors. Deviations from this rule are due to variation
of the bond forces of atoms on formation of solid soln., i.e.
mean values of thermal vibration amplitudes cannot remain
the same as in pure metal; hence the alteration of the
characteristic temp. of the alloy and of the temp. coeff.

It might be expected to fall with increasing concentration of
solid soln. As it \propto propagation velocity of elastic waves in
the crystal, it must fall with reduction of Young's modulus,
which occurs in solid soln. (as compared with the pure metal).
The reduction of characteristic temp. entails weakening of
intensity of X-ray interferences at larger angles θ . Another
reason for variation in X-ray interferences is the lattice
distortions on formation of solid soln. These facts are actually
observed, the suitability of the method for use with Cu-Zn
alloys being based on the fact of the nearly equal absorption
coeff. of the two metals for Cu radiation.

CA

Atomic dispersion of x-rays in solid solutions. V. I. Iveronova, Z. I. Kuz'mina, S. I. Futergendler, and P. I. Detairov (Moscow Univ.), *Izvist. Akad. Nauk S.S.R.*, Ser. Fiz., 15, 44-52 (1981).—Melts of Cu-Zn, KCl-KBr, and Ni-Cu of variable compn. were powd., annealed, and photographed with CuK radiation. Some tests were made at liquid-N temp. in a simple exptl. setup in which the pressure of evapg. N pressed the cooling liquid into a sidearm contg. the sample. The functions of at. dispersion are indicated for the pure compds. and the mixt. and it is shown that these functions are not additive and that the functions of solid solns. decrease faster with the angle θ than those of the pure components. In Ni-Cu alloys this has been found to be due to statistical local displacements of atoms from equil. conditions, whereas in KCl-KBr the reason for the deviation is a lowering of the characteristic temp. θ due to a change of binding forces between atoms in the lattice.

A review of the state of the theory of dislocation in a crystalline lattice. V. I. Iversonova (M. V. Lomonosov State Univ., Moscow). Izv. Akad. Nauk S.S.R., Ser. Fiz. 17, 230-30 (1953).—After a brief review of dislocation theory the concept of pos. and neg. dislocations is applied to recovery (gradual migration of dislocations) and recrystn. (change of the boundary by simultaneous movement of all dislocations). Exptl. data confirming dislocation theory are described. The crit. cleavage stress can be calcd. as a function of the distance between the planes contg. dislocations and their d.; for a stress of 6000 g./sq. mm., a distance of 10^{-4} cm. the d. is 10^{10} . Dislocation models of Taylor, Burgers, and Kochendorfer are discussed. An energy scheme of the hardening mechanism is given, and the growth of screw-type crystals from the vapor phase is treated from the standpoint of dislocation theory.

D ✓ Distortion of crystal lattice in solid solutions. V. Iveronova, Trudy Inst. Metal. Akad. Nauk SSSR, No. 10, 1957; cf. C.R. Acad. 170(1964). - Empirical data on Ni-Cu, Cu-Zn, Cu-Al, Fe-Pd, Fe-Si, and KCl-KBr systems show that: Entry into solid soln. strongly increases crit. shear stress. Hardening following deformation is less for monocrystals, the greater is the initial rate of crit. shearing stress. For polycryst. solid solns. the resultant hardening is greater, the greater is the concen. of solid soln. Limit of increase of crit. shear stress takes place with increase of concen. of solid soln. Latent surface of slip is strengthened more than the actual one, and because of this, rupture occurs earlier and the stress must be increased more strongly to pass over to another system of slippage. Increase of hardness and crit. shear stress are not connected with increase in modulus of elasticity. In solid solns. there is always the appearance of static lattice shifts. In a no. of cases there is also a dynamic shift, whose magnitude can exceed the static shifts. When the root-mean-square shifts exceed the difference in at. radii, there is evidence of chem. reaction in solid solns. V. N. Bedaarski

Original Periodical: Dokl. AN SSSR, 1954, Vol 99, No 3, 391-394

Abstract: The distortions in the crystal lattices of Fe-Pd (4 at percent Pd) and Fe-Co (5, 10, 20, 30, 35, and 50 at percent Co) alloys have been studied. The existence of distortions and their nature were investigated by the weakening of the atomic scattering function (f-curve) of the alloys indicated by comparing it with the values for the pure metals at various temperatures. The f-curve was calculated from X-ray photographs obtained by the standard powder method with Fe-K α and Co-K α radiation. An increase was detected in the distortion in Fe-Co alloys when the Co concentration was increased up to 20%, after

TITLE: The distortion of the crystal lattice in solid solutions.
(Iskazheniya kristallicheskoy reshetki v tverdykh
rastvorakh)

PERIODICAL: "Kristallografiya" (Crystallography), 1957,
Vol.2, No.3, pp. 414 - 418 (U.S.S.R.)

ABSTRACT: The values of the mean square static displacement of atoms were calculated by means of the elastic model of solid solution. A comparison of the results of calculations with the experimentally measured values of U_{st}^2 are given. The values of U_{st} determined experimentally agree in order of magnitude with the calculated values; however, the theoretically required proportionality in the difference of atomic radii is not observed. An analysis of the probable causes of this divergence is given. The most essential must be the comparison of the values of the mean square displacements with the short-range order, determined according to the intensity of the background of the X-ray pattern.

The dependence of the value of the mean square static displacements was studied in Cu-Sn, Fe-Co, Ni-Cr, Ni-Ti and Fe-C alloys. For low concentrations all the curves show a

Card 1/2

70-3-15/20

The distortion of the crystal lattice in solid solution.
(Cont.)

linear dependence of a on concentration, which agrees with the calculations carried out on the ground of the elastic model. A saturation of the value of the mean square static displacements is observed at high concentrations; for Ni-Fe alloys the outline $a = f(c)$ was obtained, which does not coincide with the theory. It was shown that in this case the values of U_{st}^2 , determined from X-ray patterns, with Mo and Cu radiation do not show mutual agreement. The picture observed is explained by the influence of primary extinction.

A curve of the dependence of the Debye temperature upon concentrations was deduced for Ni-Fe alloys. Using Cu-Au and Ni₃Fe alloys, the dependence of the Debye temperature upon the long-range order was shown. The Debye temperature of the ordered solid solution was found to be lower than that of the disordered one. There are 4 figures and 18 references, 13 of which are Slavic.

TITLE: A Method of Determining the Amplitudes of the Thermal Vibrations of Atoms of Various Kinds in a Solid Solution
(Metod opredeleniya amplitud teplovых колебаний атомов
разного sorta v tverdom rastvore)

PERIODICAL: Kristallografiya, 1957, Vol.2, No.5, pp. 613 - 617 (USSR)

ABSTRACT: An X-ray method for calculating the temperature factors B_1 and B_2 (mean square displacements) for each of two kinds of atoms has been developed and applied to an ordered solid solution, Cu₃Au, and a 1.9% solution of W in Fe. The r.m.s. amplitudes were found to be 0.18 and 0.12 Å for Cu and Au, respectively at 240 K and 0.11 and 0.05 Å for Fe and W, respectively, at 425 K. If $n = \sin^2 \theta / \lambda^2$ the atomic scattering factor for a solid solution can be expressed as:

$$f = (1 - c)f_1 \exp(-B_1 n) + cf_2 \exp(-B_2 n).$$

c is the concentration of the second component. Any pair of experimentally measured intensities $I(n)$ can be solved for B_1 and B_2 if the structure factors are calculable. The

card 1/3

70-5-7/31

A Method of Determining the Amplitudes of the Thermal Vibrations
of Atoms of Various Kinds in a Solid Solution.

equations can be expressed in terms of one variable B_1 :

$$f'' = (1-c)f_1'' \exp(-B_1 n'') + cf_2'' \left[\{ f' - (1-c)f_1'' \exp(-B_1 n') \} / cf_2' \right]^{n''/n}$$

This expression is plotted out for Cu₃Au for different pairs of n' and n'' . The Cu₃Au was only partly ordered so that the static distortion ($\alpha_{st.} = 0.66$) was eliminated by taking photographs at two different temperatures which gave $B = 0.60$. Introducing the parameter α , correction can be made for the different types of bonds to the solute atoms. The dependence of α on B_x , (r.m.s. amplitude of the solute atom) can be found by constructing the family of curves of f against B_x for different values of α . The observed dependence of f on $\sin\theta/\lambda$ enables the curve $\alpha(B_x)$ to be found.

There are 2 figures, 3 tables and 3 non-Slavic references.
